# The `l3str` package: manipulating strings of characters<sup>\*</sup>

The L<sup>A</sup>T<sub>E</sub>X3 Project<sup>†</sup>

Released 2012/07/09

L<sup>A</sup>T<sub>E</sub>X3 provides a set of functions to manipulate token lists as strings of characters, ignoring the category codes of those characters.

String variables are simply specialised token lists, but by convention should be named with the suffix `...str`. Such variables should contain characters with category code 12 (other), except spaces, which have category code 10 (blank space). All the functions in this module first convert their argument to a string for internal processing, and will not treat a token list or the corresponding string representation differently.

Most functions in this module come in three flavours:

- `\str...:N...`, which expect a token list or string variable as their argument;
- `\str...:n...`, taking any token list (or string) as an argument;
- `\str..._ignore_spaces:n...`, which ignores any space encountered during the operation: these functions are faster than those which take care of escaping spaces appropriately;

## 1 Building strings

---

`\c_max_char_int`

---

The maximum valid character code, 255 for pdfT<sub>E</sub>X, and 1114111 for X<sub>Ǝ</sub>T<sub>E</sub>X and LuaT<sub>E</sub>X.

---

`\c_backslash_str`  
`\c_lbrace_str`  
`\c_rbrace_str`  
`\c_hash_str`  
`\c_tilde_str`  
`\c_percent_str`

---

Constant strings, containing a single character, with category code 12. Any character can be accessed as `\iow_char:N \langle character \rangle`.

---

<sup>\*</sup>This file describes v3940, last revised 2012/07/09.

<sup>†</sup>E-mail: [latex-team@latex-project.org](mailto:latex-team@latex-project.org)

---

<code>\tl_to_str:N</code>	★	<code>\tl_to_str:N &lt;tl var&gt;</code>
<code>\tl_to_str:n</code>	★	<code>\tl_to_str:n {\token list}</code>

---

Converts the  $\langle token list \rangle$  to a  $\langle string \rangle$ , leaving the resulting tokens in the input stream.

**T<sub>E</sub>Xhackers note:** The string representation of a token list may depend on the category codes in effect when it is evaluated, and the value of the `\escapechar`: for instance `\tl_to_str:n {\a}` normally produces the three character “backslash”, “lower-case a”, “space”, but it may also produce 1 or 2 characters depending on the escape character, and the category code of `a`. This impacts almost all functions in the module, which use `\tl_to_str:n` internally.

---

<code>\str_new:N</code>	<code>\str_new:N &lt;str var&gt;</code>
<code>\str_new:c</code>	

---

Creates a new  $\langle str var \rangle$  or raises an error if the name is already taken. The declaration is global. The  $\langle str var \rangle$  will initially be empty.

---

<code>\str_const:Nn</code>	<code>\str_const:Nn &lt;str var&gt; {\token list}</code>
<code>\str_const:(Nx cn cx)</code>	

---

Creates a new constant  $\langle str var \rangle$  or raises an error if the name is already taken. The value of the  $\langle str var \rangle$  will be set globally to the  $\langle token list \rangle$ , converted to a string.

---

<code>\str_set:Nn</code>	<code>\str_set:Nn &lt;str var&gt; {\token list}</code>
<code>\str_set:(Nx cn cx)</code>	
<code>\str_gset:Nn</code>	
<code>\str_gset:(Nx cn cx)</code>	

---

Converts the  $\langle token list \rangle$  to a  $\langle string \rangle$ , and stores the result in  $\langle str var \rangle$ .

---

<code>\str_put_left:Nn</code>	<code>\str_put_left:Nn &lt;str var&gt; {\token list}</code>
<code>\str_put_left:(Nx cn cx)</code>	
<code>\str_gput_left:Nn</code>	
<code>\str_gput_left:(Nx cn cx)</code>	

---

Converts the  $\langle token list \rangle$  to a  $\langle string \rangle$ , and prepends the result to  $\langle str var \rangle$ . The current contents of the  $\langle str var \rangle$  are not automatically converted to a string.

---

<code>\str_put_right:Nn</code>	<code>\str_put_right:Nn &lt;str var&gt; {\token list}</code>
<code>\str_put_right:(Nx cn cx)</code>	
<code>\str_gput_right:Nn</code>	
<code>\str_gput_right:(Nx cn cx)</code>	

---

Converts the  $\langle token list \rangle$  to a  $\langle string \rangle$ , and appends the result to  $\langle str var \rangle$ . The current contents of the  $\langle str var \rangle$  are not automatically converted to a string.

## 2 Accessing the contents of a string

---

<code>\str_count:N</code>	★	<code>\str_count:n {\token list}</code>
<code>\str_count:n</code>	★	
<code>\str_count_ignore_spaces:n</code>	★	

---

Leaves the number of tokens in the string representation of  $\langle token list \rangle$  in the input stream as an integer denotation. The functions differ in their treatment of spaces. In the case of `\str_count:N` and `\str_count:n`, all characters including spaces are counted. The `\str_count_ignore_spaces:n` leaves the number of non-space characters in the input stream.

---

<code>\str_count_spaces:N</code>	★	<code>\str_count_spaces:n</code>	{ <i>token list</i> }
<code>\str_count_spaces:n</code>	★		

---

Leaves in the input stream the number of space characters in the string representation of *token list*, as an integer denotation. Of course, this function has no `_ignore_spaces` variant.

---

<code>\str_head:N</code>	★	<code>\str_head:n</code>	{ <i>token list</i> }
<code>\str_head:n</code>	★		
<code>\str_head_ignore_spaces:n</code>	★		

---

Converts the *token list* into a *string*. The first character in the *string* is then left in the input stream, with category code “other”. The functions differ in their treatment of spaces. In the case of `\str_head:N` and `\str_head:n`, a leading space is returned with category code 10 (blank space). The `\str_head_ignore_spaces:n` function leaves the first non-space character in the input stream. If the *token list* is empty (or blank in the case of the `_ignore_spaces` variant), then nothing is left on the input stream.

---

<code>\str_tail:N</code>	★	<code>\str_tail:n</code>	{ <i>token list</i> }
<code>\str_tail:n</code>	★		
<code>\str_tail_ignore_spaces:n</code>	★		

---

Converts the *token list* to a *string*, removes the first character, and leaves the remaining characters (if any) in the input stream, with category codes 12 and 10 (for spaces). The functions differ in the case where the first character is a space: `\str_tail:N` and `\str_tail:n` will trim only that space, while `\str_tail_ignore_spaces:n` removes the first non-space character and any space before it. If the *token list* is empty (or blank in the case of the `_ignore_spaces` variant), then nothing is left on the input stream.

---

<code>\str_item:Nn</code>	★	<code>\str_item:nn</code>	{ <i>token list</i> } { <i>integer expression</i> }
<code>\str_item:nn</code>	★		
<code>\str_item_ignore_spaces:nn</code>	★		

---

Converts the *token list* to a *string*, and leaves in the input stream the character in position *integer expression* of the *string*. In the case of `\str_item:Nn` and `\str_item:nn`, all characters including spaces are taken into account. The `\str_item_ignore_spaces:nn` function skips spaces in its argument. If the *integer expression* is negative, characters are counted from the end of the *string*. Hence,  $-1$  is the right-most character, *etc.*, while  $1$  is the first (left-most) character.

---

<code>\str_substr:Nnn</code>	★	<code>\str_substr:nnn {⟨token list⟩} {⟨start index⟩} {⟨end index⟩}</code>
<code>\str_substr:nnn</code>	★	
<code>\str_substr_ignore_spaces:nnn</code>	★	

---

Converts the  $\langle token\ list \rangle$  to a  $\langle string \rangle$ , and leaves in the input stream the characters from the  $\langle start\ index \rangle$  inclusive to the  $\langle end\ index \rangle$  exclusive. Note that the token count of the substring is equal to the difference between the two  $\langle indices \rangle$ . If either of  $\langle start\ index \rangle$  or  $\langle end\ index \rangle$  is negative, then it is incremented by the token count of the list. If either of  $\langle start\ index \rangle$  or  $\langle end\ index \rangle$  is empty, it is replaced by the corresponding end-point of the string. Both  $\langle start\ index \rangle$  and  $\langle end\ index \rangle$  count from 1 for the first (left most) character. For instance,

```
\iow_term:x { \str_substr:nnn { abcdef } { 2 } { 5 } }
\iow_term:x { \str_substr:nnn { abcdef } { -4 } { } }
```

will print bcd and cdef to the terminal.

### 3 String conditionals

---

<code>\str_if_eq_p:nn</code>	★	<code>\str_if_eq_p:nn {⟨t<sub>1</sub>⟩} {⟨t<sub>2</sub>⟩}</code>
<code>\str_if_eq_p:(Vn on no nV VV)</code>	★	<code>\str_if_eq:nnTF {⟨t<sub>1</sub>⟩} {⟨t<sub>2</sub>⟩} {⟨true code⟩} {⟨false code⟩}</code>
<code>\str_if_eq:nnTF</code>	★	
<code>\str_if_eq:(Vn on no nV VV)TF</code>	★	

---

Compares the two  $\langle token\ lists \rangle$  on a character by character basis, and is **true** if the two lists contain the same characters in the same order. Thus for example

```
\str_if_eq_p:no { abc } { \tl_to_str:n { abc } }
```

is logically **true**.

---

<code>\str_if_eq_x_p:nn</code>	★	<code>\str_if_eq_x_p:nn {⟨t<sub>1</sub>⟩} {⟨t<sub>2</sub>⟩}</code>
<code>\str_if_eq_x:nnTF</code>	★	<code>\str_if_eq_x:nnTF {⟨t<sub>1</sub>⟩} {⟨t<sub>2</sub>⟩} {⟨true code⟩} {⟨false code⟩}</code>

---

New: 2012-06-05

Compares the full expansion of two  $\langle token\ lists \rangle$  on a character by character basis, and is **true** if the two lists contain the same characters in the same order. Thus for example

```
\str_if_eq_x_p:nn { abc } { \tl_to_str:n { abc } }
```

is logically **true**.

---

<code>\str_case:nnn</code> ★	<code>\str_case:nnn {⟨test string⟩}</code>
<code>\str_case:onn</code> ★	<code>{</code>
	<code>  {⟨string case1⟩} {⟨code case1⟩}</code>
	<code>  {⟨string case2⟩} {⟨code case2⟩}</code>
	<code>  ...</code>
	<code>  {⟨string case<sub>n</sub>⟩} {⟨code case<sub>n</sub>⟩}</code>
	<code>}</code>
	<code>{⟨else case⟩}</code>

---

New: 2012-06-03

This function compares the  $\langle test\ string \rangle$  in turn with each of the  $\langle string\ cases \rangle$ . If the two are equal (as described for `\str_if_eq:nnTF`) then the associated  $\langle code \rangle$  is left in the input stream. If none of the tests are `true` then the `else` code will be left in the input stream.

---

<code>\str_case_x:nnn</code> ★	<code>\str_case_x:nnn {⟨test string⟩}</code>
	<code>{</code>
	<code>  {⟨string case1⟩} {⟨code case1⟩}</code>
	<code>  {⟨string case2⟩} {⟨code case2⟩}</code>
	<code>  ...</code>
	<code>  {⟨string case<sub>n</sub>⟩} {⟨code case<sub>n</sub>⟩}</code>
	<code>}</code>
	<code>{⟨else case⟩}</code>

---

New: 2012-06-05

This function compares the full expansion of the  $\langle test\ string \rangle$  in turn with the full expansion of the  $\langle string\ cases \rangle$ . If the two full expansions are equal (as described for `\str_if_eq:nnTF`) then the associated  $\langle code \rangle$  is left in the input stream. If none of the tests are `true` then the `else` code will be left in the input stream. The  $\langle test\ string \rangle$  is expanded in each comparison, and must always yield the same result: for example, random numbers must not be used within this string.

## 4 Viewing strings

---

<code>\str_show:N</code>	<code>\str_show:N ⟨t1 var⟩</code>
<code>\str_show:(c n)</code>	Displays the content of the $\langle str\ var \rangle$ on the terminal.

---

## 5 Scratch strings

---

<code>\l_tmpa_str</code>	Scratch strings for local assignment. These are never used by the kernel code, and so
<code>\l_tmpb_str</code>	are safe for use with any L <sup>A</sup> T <sub>E</sub> X3-defined function. However, they may be overwritten by
	other non-kernel code and so should only be used for short-term storage.

---

---

<code>\g_tmpa_str</code>	Scratch strings for global assignment. These are never used by the kernel code, and so
<code>\g_tmpb_str</code>	are safe for use with any L <sup>A</sup> T <sub>E</sub> X3-defined function. However, they may be overwritten by
	other non-kernel code and so should only be used for short-term storage.

---

Table 1: Supported encodings. Non-alphanumeric characters are ignored, and capital letters are lower-cased before searching for the encoding in this list.

$\langle Encoding \rangle$	description
utf8	UTF-8
utf16	UTF-16, with byte-order mark
utf16be	UTF-16, big-endian
utf16le	UTF-16, little-endian
utf32	UTF-32, with byte-order mark
utf32be	UTF-32, big-endian
utf32le	UTF-32, little-endian
iso88591, latin1	ISO 8859-1
iso88592, latin2	ISO 8859-2
iso88593, latin3	ISO 8859-3
iso88594, latin4	ISO 8859-4
iso88595	ISO 8859-5
iso88596	ISO 8859-6
iso88597	ISO 8859-7
iso88598	ISO 8859-8
iso88599, latin5	ISO 8859-9
iso885910, latin6	ISO 8859-10
iso885911	ISO 8859-11
iso885913, latin7	ISO 8859-13
iso885914, latin8	ISO 8859-14
iso885915, latin9	ISO 8859-15
iso885916, latin10	ISO 8859-16
Empty	Native (Unicode) string.

## 6 Encoding functions

Traditionally, string encodings only specify how strings of characters should be stored as bytes. However, the resulting lists of bytes are often to be used in contexts where only a restricted subset of bytes are permitted (*e.g.*, PDF string objects, URLs). Hence, storing a string of characters is done in two steps.

- The code points (“character codes”) are expressed as bytes following a given “encoding”. This can be UTF-16, ISO 8859-1, *etc.* See Table 1 for a list of supported encodings.<sup>1</sup>
- Bytes are translated to T<sub>E</sub>X tokens through a given “escaping”. Those are defined for the most part by the pdf file format. See Table 2 for a list of escaping methods supported.<sup>2</sup>

<sup>1</sup>Encodings and escapings will be added as they are requested.

Table 2: Supported escapings. Non-alphanumeric characters are ignored, and capital letters are lower-cased before searching for the escaping in this list.

$\langle Escaping \rangle$	description
bytes, or empty	arbitrary bytes
hex, hexadecimal	byte = two hexadecimal digits
name	see <code>\pdfescapename</code>
string	see <code>\pdfescapestring</code>
url	encoding used in URLs

---

`\str_set_convert:Nnnn`  
`\str_gset_convert:Nnnn`

---

`\str_set_convert:Nnnn`  $\langle str\ var \rangle$   $\{\langle string \rangle\}$   $\{\langle name\ 1 \rangle\}$   $\{\langle name\ 2 \rangle\}$

This function converts the  $\langle string \rangle$  from the encoding given by  $\langle name\ 1 \rangle$  to the encoding given by  $\langle name\ 2 \rangle$ , and stores the result in the  $\langle str\ var \rangle$ . Each  $\langle name \rangle$  can have the form  $\langle encoding \rangle$  or  $\langle encoding \rangle / \langle escaping \rangle$ , where the possible values of  $\langle encoding \rangle$  and  $\langle escaping \rangle$  are given in Tables 1 and 2, respectively. The default escaping is to input and output bytes directly. The special case of an empty  $\langle name \rangle$  indicates the use of “native” strings, 8-bit for pdfTeX, and Unicode strings for the other two engines.

For example,

`\str_set_convert:Nnnn \l_foo_str { Hello! } { } { utf16/hex }`

results in the variable `\l_foo_str` holding the string `FEFF00480065006C006F0021`. This is obtained by converting each character in the (native) string `Hello!` to the UTF-16 encoding, and expressing each byte as a pair of hexadecimal digits. Note the presence of a (big-endian) byte order mark “FEFF”, which can be avoided by specifying the encoding `utf16be/hex`.

An error is raised if the  $\langle string \rangle$  is not valid according to the  $\langle escaping\ 1 \rangle$  and  $\langle encoding\ 1 \rangle$ , or if it cannot be reencoded in the  $\langle encoding\ 2 \rangle$  and  $\langle escaping\ 2 \rangle$  (for instance, if a character does not exist in the  $\langle encoding\ 2 \rangle$ ). Erroneous input is replaced by the Unicode replacement character “FFFD”, and characters which cannot be reencoded are replaced by either the replacement character “FFFD” if it exists in the  $\langle encoding\ 2 \rangle$ , or an encoding-specific replacement character, or the question mark character.

---

`\str_set_convert:NnnnTF`  
`\str_gset_convert:NnnnTF`

---

`\str_set_convert:NnnnTF`  $\langle str\ var \rangle$   $\{\langle string \rangle\}$   $\{\langle name\ 1 \rangle\}$   $\{\langle name\ 2 \rangle\}$   $\{\langle true\ code \rangle\}$   
 $\{\langle false\ code \rangle\}$

As `\str_set_convert:Nnnn`, converts the  $\langle string \rangle$  from the encoding given by  $\langle name\ 1 \rangle$  to the encoding given by  $\langle name\ 2 \rangle$ , and assigns the result to  $\langle str\ var \rangle$ . Contrarily to `\str_set_convert:Nnnn`, the conditional variant does not raise errors in case the  $\langle string \rangle$  is not valid according to the  $\langle name\ 1 \rangle$  encoding, or cannot be expressed in the  $\langle name\ 2 \rangle$  encoding. Instead, the  $\langle false\ code \rangle$  is performed.

## 7 Internal string functions

---

`\__str_gset_other:Nn`

---

`\__str_gset_other:Nn <tl var> {<token list>}`

Converts the *<token list>* to an *<other string>*, where spaces have category code “other”, and assigns the result to the *<tl var>*, globally.

---

`\__str_hexadecimal_use:NTF`

---

`\__str_hexadecimal_use:NTF <token> {<true code>} {<false code>}`

If the *<token>* is a hexadecimal digit (upper case or lower case), its upper-case version is left in the input stream, *followed* by the *<true code>*. Otherwise, the *<false code>* is left in the input stream.

**T<sub>E</sub>Xhackers note:** This function fails on some inputs if the escape character is a hexadecimal digit. We are thus careful to set the escape character to a known (safe) value before using it.

---

`\__str_output_byte:n` ★

---

`\__str_output_byte:n {<intexpr>}`

Expands to a character token with category other and character code equal to the value of *<intexpr>*. The value of *<intexpr>* must be in the range  $[-1, 255]$ , and any value outside this range results in undefined behaviour. The special value  $-1$  is used to produce an empty result.

## 8 Possibilities, and things to do

Encoding/escaping-related tasks.

- Describe the internal format in the code comments. Refuse code points in `["D800", "DFFF]` in the internal representation?
- Add documentation about each encoding and escaping method, and add examples.
- The `hex` unescaping should raise an error for odd-token count strings.
- Decide what bytes should be escaped in the `url` escaping. Perhaps `!'()*-./0123456789_` are safe, and all other characters should be escaped?
- Automate generation of 8-bit mapping files.
- Change the framework for 8-bit encodings: for decoding from 8-bit to Unicode, use 256 integer registers; for encoding, use a tree-box.
- More encodings (see Heiko’s `stringenc`). CESU?
- More escapings: shell escapes, lua escapes, etc?

Other string tasks.

- Expandable `\str_if_in:nnTF?`
- `\str_if_head_eq:nN`
- `\str_if_numeric/decimal/integer:n`, perhaps in `l3fp?`
- Should `\str_item:Nn` be `\str_char:Nn`?
- Should `\str_substr:Nnn` be `\str_range:Nnn`?
- Introduce `\str_slice:Nnnn` with a third “step” argument? Or should we simply have `\str_slice:Nn <string> {<clist>}`, where the `<clist>`’s items are either one integer expression, two integer expressions separated by `:`, or three integer expressions separated by `:`, *cf.* Python’s extended slice syntax?
- Analog of `printf`?

## 9 l3str implementation

```

1 <*initex | package>
2 <@@=str>
3 \ProvidesExplPackage
4   {\ExplFileName}{\ExplFileDate}{\ExplFileVersion}{\ExplFileDescription}
5 \RequirePackage{l3tl-analysis,l3tl-build,l3flag}

```

The following string-related functions are currently defined in `l3kernel`.

- `\str_if_eq:nn[pTF]` and variants,
- `\str_if_eq_x_return:on`, `\str_if_eq_x_return:nn`
- `\tl_to_str:n`, `\tl_to_str:N`, `\tl_to_str:c`,
- `\token_to_str:N`, `\cs_to_str:N`
- `\str_head:n`, `\_str_head:w`, (copied here)
- `\str_tail:n`, `\_str_tail:w`, (copied here)
- `\str_count_ignore_spaces` (unchanged)
- `\str_count_loop:NNNNNNNN` (unchanged)

### 9.1 Helpers

#### 9.1.1 A function unrelated to strings

```

\use_ii_i:nn A function used to swap its arguments.
6 \cs_if_exist:NF \use_ii_i:nn
7   { \cs_new:Npn \use_ii_i:nn #1#2 { #2 #1 } }
(End definition for \use_ii_i:nn)

```

### 9.1.2 Assigning strings

**\str\_new:N** A string is simply a token list.

**\str\_new:c** 8 \cs\_new\_eq:NN \str\_new:N \tl\_new:N  
9 \cs\_generate\_variant:Nn \str\_new:N { c }

(End definition for \str\_new:N and \str\_new:c These functions are documented on page ??.)

**\str\_set:Nn** Simply convert the token list inputs to  $\langle strings \rangle$ .

**\str\_set:Nx** 10 \tl\_map\_inline:nn

**\str\_set:cn** 11 {

**\str\_set:cx** 12 { set }

**\str\_gset:Nn** 13 { gset }

**\str\_gset:Nx** 14 { const }

**\str\_gset:cn** 15 { put\_left }

**\str\_gset:cx** 16 { gput\_left }

**\str\_const:Nn** 17 { put\_right }

**\str\_const:Nx** 18 { gput\_right }

**\str\_const:cn** 19 }

**\str\_const:cx** 20 {

**\str\_put\_left:Nn** 21 \cs\_new\_protected:cpx { str\_ #1 :Nn } ##1##2  
22 { \exp\_not:c { tl\_ #1 :Nx } ##1 { \exp\_not:N \tl\_to\_str:n {##2} } }

**\str\_put\_left:Nx** 23 \exp\_args:Nc \cs\_generate\_variant:Nn { str\_ #1 :Nn } { Nx , cn , cx }

**\str\_put\_left:cn** 24 }

**\str\_put\_left:cx** (End definition for \str\_set:Nn and others. These functions are documented on page ??.)

**\str\_gput\_left:Nn**

**\str\_gput\_left:Nx**

**\str\_gput\_left:cn**

**\str\_gput\_left:cx**

### 9.1.3 Variables and constants

Internal scratch space for some functions.

25 \cs\_new\_protected\_nopar:Npn \\_\_str\_tmp:w { }

26 \tl\_new:N \l\_\_str\_internal\_tl

27 \int\_new:N \l\_\_str\_internal\_int

(End definition for \\_\_str\_tmp:w This function is documented on page ??.)

**\str\_gput\_right:Nn**

**\g\_\_str\_result\_tl**

**\str\_gput\_right:Nx**

**\str\_gput\_right:cn**

**\str\_gput\_right:cx**

The  $\backslash g\_str\_result\_tl$  variable is used to hold the result of various internal string operations (mostly conversions) which are typically performed in a group. The variable is global so that it remains defined outside the group, to be assigned to a user-provided variable.

28 \tl\_new:N \g\_\_str\_result\_tl

(End definition for  $\backslash g\_str\_result\_tl$  This variable is documented on page ??.)

**\c\_forty\_eight**

**\c\_fifty\_eight**

**\c\_sixty\_five**

**\c\_ninety\_one**

**\c\_ninety\_seven**

We declare here some integer values which delimit ranges of ASCII characters of various types. This is mostly used in l3regex.

29 \int\_const:Nn \c\_forty\_eight { 48 }

30 \int\_const:Nn \c\_fifty\_eight { 58 }

31 \int\_const:Nn \c\_sixty\_five { 65 }

32 \int\_const:Nn \c\_ninety\_one { 91 }

33 \int\_const:Nn \c\_ninety\_seven { 97 }

34 \int\_const:Nn \c\_one\_hundred\_twenty\_three { 123 }

35 \int\_const:Nn \c\_one\_hundred\_twenty\_seven { 127 }

**\c\_one\_hundred\_twenty\_three**

**\c\_one\_hundred\_twenty\_seven**

(End definition for `\c_forty_eight` and others. These variables are documented on page ??.)

`\c_max_char_int` The maximum valid character code is 255 for pdfTeX, and 1114111 for other engines.

```
36 \int_const:Nn \c_max_char_int
37 { \pdfTeX_if_engine:TF { "FF } { "10FFFF } }
```

(End definition for `\c_max_char_int` This variable is documented on page 2.)

`\c__str_replacement_char_int` When converting, invalid bytes are replaced by the Unicode replacement character "FFFD.

```
38 \int_const:Nn \c__str_replacement_char_int { "FFFD }
```

(End definition for `\c__str_replacement_char_int` This variable is documented on page ??.)

`\c_backslash_str` `\c_lbrace_str` `\c_rbrace_str` `\c_hash_str` `\c_tilde_str` `\c_percent_str` For all of those strings, use `\cs_to_str:N` to get characters with the correct category code.

```
39 \tl_const:Nx \c_backslash_str { \cs_to_str:N \ }
40 \tl_const:Nx \c_lbrace_str { \cs_to_str:N { }
41 \tl_const:Nx \c_rbrace_str { \cs_to_str:N } }
42 \tl_const:Nx \c_hash_str { \cs_to_str:N # }
43 \tl_const:Nx \c_tilde_str { \cs_to_str:N ~ }
44 \tl_const:Nx \c_percent_str { \cs_to_str:N % }
```

(End definition for `\c_backslash_str` and others. These variables are documented on page 2.)

`\g__str_alias_prop` To avoid needing one file per encoding/escaping alias, we keep track of those in a property list.

```
45 \prop_new:N \g__str_alias_prop
46 \prop_gput:Nnn \g__str_alias_prop { latin1 } { iso88591 }
47 \prop_gput:Nnn \g__str_alias_prop { latin2 } { iso88592 }
48 \prop_gput:Nnn \g__str_alias_prop { latin3 } { iso88593 }
49 \prop_gput:Nnn \g__str_alias_prop { latin4 } { iso88594 }
50 \prop_gput:Nnn \g__str_alias_prop { latin5 } { iso88599 }
51 \prop_gput:Nnn \g__str_alias_prop { latin6 } { iso885910 }
52 \prop_gput:Nnn \g__str_alias_prop { latin7 } { iso885913 }
53 \prop_gput:Nnn \g__str_alias_prop { latin8 } { iso885914 }
54 \prop_gput:Nnn \g__str_alias_prop { latin9 } { iso885915 }
55 \prop_gput:Nnn \g__str_alias_prop { latin10 } { iso885916 }

57 \prop_gput:Nnn \g__str_alias_prop { utf16be } { utf16 }
58 \prop_gput:Nnn \g__str_alias_prop { utf32le } { utf32 }
59 \prop_gput:Nnn \g__str_alias_prop { utf32be } { utf32 }
60 \prop_gput:Nnn \g__str_alias_prop { hexadecimal } { hex }
```

(End definition for `\g__str_alias_prop` This variable is documented on page ??.)

`\g__str_error_bool` In conversion functions with a built-in conditional, errors are not reported directly to the user, but the information is collected in this boolean, used at the end to decide on which branch of the conditional to take.

```
61 \bool_new:N \g__str_error_bool
```

(End definition for `\g__str_error_bool` This variable is documented on page ??.)

**str\_byte** Conversions from one *<encoding>/<escaping>* pair to another are done within **x**-expanding assignments. Errors are signalled by raising the relevant flag.

```
62 \flag_new:n { str_byte }
63 \flag_new:n { str_error }
```

(End definition for **str\_byte** and **str\_error** These variables are documented on page ??.)

#### 9.1.4 Escaping spaces

**\\_\_str\_to\_other:n** Converts the *<token list>* to a *<other string>*, where spaces have category code “other”. First apply **\tl\_to\_str:n**, then replace all spaces by “other” spaces, 8 at a time, storing the converted part of the string between the **\q\_mark** and **\q\_stop** markers. This function can be **f**-expanded without fear of losing a leading space, since spaces do not have category code 10 in its result. This function takes a time quadratic in the token count of the string; **\\_\_str\_gset\_other:Nn** is faster but not expandable.

```
64 \group_begin:
65 \char_set_lccode:nn { '\* } { '\ }
66 \char_set_lccode:nn { '\A } { '\A }
67 \tl_to_lowercase:n
68 {
69   \group_end:
70   \cs_new:Npn \__str_to_other:n #1
71   {
72     \exp_after:wN \__str_to_other_loop:w \tl_to_str:n {#1} ~ %
73     A ~ A ~ A ~ A ~ A ~ A ~ A ~ A ~ \q_mark \q_stop
74   }
75   \cs_new:Npn \__str_to_other_loop:w
76   #1 ~ #2 ~ #3 ~ #4 ~ #5 ~ #6 ~ #7 ~ #8 ~ #9 \q_stop
77   {
78     \if_meaning:w A #8
79     \__str_to_other_end:w
80     \fi:
81     \__str_to_other_loop:w
82     #9 #1 * #2 * #3 * #4 * #5 * #6 * #7 * #8 * \q_stop
83   }
84   \cs_new:Npn \__str_to_other_end:w \fi: #1 \q_mark #2 * A #3 \q_stop
85   { \fi: #2 }
86 }
```

(End definition for **\\_\_str\_to\_other:n** This function is documented on page ??.)

**\\_\_str\_gset\_other:Nn** This function could be done by using **\\_\_str\_to\_other:n** within an **x**-expansion, but that would take a time quadratic in the size of the string. Instead, we can “leave the result behind us” in the input stream, to be captured into the expanding assignment. This gives us a linear time.

```
87 \group_begin:
88 \char_set_lccode:nn { '\* } { '\ }
89 \char_set_lccode:nn { '\A } { '\A }
90 \tl_to_lowercase:n
91 {
```

```

92 \group_end:
93 \cs_new_protected:Npn \__str_gset_other:Nn #1#2
94 {
95   \tl_gset:Nx #1
96   {
97     \exp_after:wN \__str_gset_other_loop:w \tl_to_str:n {#2} ~ %
98     A ~ A ~ A ~ A ~ A ~ A ~ A ~ A ~ A ~ \q_stop
99   }
100 }
101 \cs_new:Npn \__str_gset_other_loop:w
102 #1 ~ #2 ~ #3 ~ #4 ~ #5 ~ #6 ~ #7 ~ #8 ~ #9 ~
103 {
104   \if_meaning:w A #9
105     \__str_gset_other_end:w
106   \fi:
107   #1 * #2 * #3 * #4 * #5 * #6 * #7 * #8 * #9
108   \__str_gset_other_loop:w *
109 }
110 \cs_new:Npn \__str_gset_other_end:w \fi: #1 * A #2 \q_stop
111 { \fi: #1 }
112 }

```

(End definition for \\_\_str\_gset\_other:Nn This function is documented on page 9.)

## 9.2 Characters given by their position

**\str\_count\_spaces:N** To speed up this function, we grab 9 spaces in each step. The loop stops when the last argument is one of the trailing  $X\langle number \rangle$ , and that  $\langle number \rangle$  is added to the sum of 9 that preceeds, to adjust the result.

**\str\_count\_spaces:n**

```

\__str_count_spaces_loop:wwwwwww
113 \cs_new:Npn \str_count_spaces:N
114 { \exp_args:No \str_count_spaces:n }
115 \cs_new:Npn \str_count_spaces:n #1

131 }

```

(End definition for \str\_count\_spaces:N This function is documented on page ??.)

`\str_count:N` To measure the token count of a string we could first escape all spaces using `\__str_-`  
`\str_count:n` `to_other:o`, then measure the count of this token list. However, this would be quadratic  
`\__str_count_unsafe:n` in the length of the string, and we can do better. Namely, add the number of spaces  
`\str_count_ignore_spaces:n` (counted using the functions defined above) to the length ignoring spaces. To measure the  
`\__str_count:n` length ignoring spaces we use the same technique as for counting spaces: loop, grabbing  
`\__str_count_loop:NNNNNNNN` 9 characters at each step, and end as soon as we reach one of the 9 trailing items. The  
`\__str_count_loop:NNNNNNNN` `_unsafe` variant expects a token list consisting entirely of category code 12 characters.

```

132 \cs_new_nopar:Npn \str_count:N { \exp_args:No \str_count:n }
133 \cs_new:Npn \str_count:n #1

`\str_head:N` The `_ignore_spaces` variant is almost identical to `\tl_head:n`. As usual, `\str_head:N`  
`\str_head:n` expands its argument and hands it to `\str_head:n`. To circumvent the fact that  $\TeX$   
`\str_head_ignore_spaces:n`  
`\__str_head:w`

skips spaces when grabbing undelimited macro parameters, `\__str_head:w` takes an argument delimited by a space. If `#1` starts with a non-space character, `\use_i_delimit_by_q_stop:nw` leaves that in the input stream. On the other hand, if `#1` starts with a space, the `\__str_head:w` takes an empty argument, and the single (braced) space in the definition of `\__str_head:w` makes its way to the output. Finally, for an empty argument, the (braced) empty brace group in the definition of `\str_head:n` gives an empty result after passing through `\use_i_delimit_by_q_stop:nw`.

```

169 \cs_new_nopar:Npn \str_head:N { \exp_args:No \str_head:n }
170 \cs_set:Npn \str_head:n #1
171   {
172     \exp_after:wN \__str_head:w
173     \tl_to_str:n {#1}
174     { { } } ~ \q_stop
175   }
176 \cs_set:Npn \__str_head:w #1 ~ %
177   { \use_i_delimit_by_q_stop:nw #1 { ~ } }
178 \cs_new:Npn \str_head_ignore_spaces:n #1
179   {
180     \exp_after:wN \use_i_delimit_by_q_stop:nw
181     \tl_to_str:n {#1} { } \q_stop
182   }

```

(End definition for `\str_head:N` This function is documented on page 4.)

`\str_tail:N` As when fetching the head of a string, the `_ignore_spaces` variant is similar to `\tl_tail:n`. The more commonly used `\str_tail:n` function is a little bit more convoluted: hitting the front of the string with `\reverse_if:N \if_charcode:w \scan_stop:` removes the first character (which necessarily makes the test true, since it cannot match `\scan_stop:`). The auxiliary function inserts the required `\fi:` to close the conditional, and leaves the tail of the string in the input string. The details are such that an empty string has an empty tail.

```

183 \cs_new_nopar:Npn \str_tail:N { \exp_args:No \str_tail:n }
184 \cs_set:Npn \str_tail:n #1
185   {
186     \exp_after:wN \__str_tail:w
187     \reverse_if:N \if_charcode:w
188       \scan_stop: \tl_to_str:n {#1} X X \q_stop
189   }
190 \cs_set:Npn \__str_tail:w #1 X #2 \q_stop { \fi: #1 }
191 \cs_new:Npn \str_tail_ignore_spaces:n #1
192   {
193     \exp_after:wN \__str_tail_ii:w
194     \tl_to_str:n {#1} X X \q_stop
195   }
196 \cs_new:Npn \__str_tail_ii:w #1 #2 X #3 \q_stop { #2 }

```

(End definition for `\str_tail:N` This function is documented on page 4.)

`\__str_skip_c_zero:w` Removes `max(#1,0)` characters from the input stream, and then leaves `\c_zero`. This should be expanded using `\tex_romannumeral:D`. We remove characters 8 at a time until  
`\__str_skip_loop:wNNNNNNNN`  
`\__str_skip_end:w`  
`\__str_skip_end_ii:NNNNNNNN`

there are at most 8 to remove. Then we do a dirty trick: the `\if_case:w` construction leaves between 0 and 8 times the `\or:` control sequence, and those `\or:` become arguments of `__str_skip_end_ii:NNNNNNNN`. If the number of characters to remove is 6, say, then there are two `\or:` left, and the 8 arguments of `__str_skip_end_ii:NNNNNNNN` are the two `\or:`, and 6 characters from the input stream, exactly what we wanted to remove. Then close the `\if_case:w` conditional with `\fi:`, and stop the initial expansion with `\c_zero` (see places where `__str_skip_c_zero:w` is called).

```

197 \cs_new:Npn __str_skip_c_zero:w #1;
198 {
199     \if_int_compare:w __int_eval:w #1 > \c_eight

213     \or: \or: \or: \or: \or: \or: \or: \or:
214 }
215 \cs_new:Npn __str_skip_end_ii:NNNNNNNN #1#2#3#4#5#6#7#8 { \fi: \c_zero }

```

(End definition for `__str_skip_c_zero:w` This function is documented on page ??.)

`__str_collect_delimit_by_q_stop:w` Collects `max(#1,0)` characters, and removes everything else until `\q_stop`. This is somewhat similar to `__str_skip_c_zero:w`, but this time we can only grab 7 characters at a time. At the end, we use an `\if_case:w` trick again, so that the 8 first arguments of `__str_collect_end_ii:nnnnnnnnw` are some `\or:`, followed by an `\fi:`, followed by `#1` characters from the input stream. Simply leaving this in the input stream will close the conditional properly and the `\or:` disappear.

```

216 \cs_new:Npn __str_collect_delimit_by_q_stop:w #1;
217 {
218     \exp_after:wN __str_collect_loop:wN

(End definition for `\str_substr:Nnn` This function is documented on page 5.)

### 9.3 String conditionals

`\str_if_eq_p:NN` Note that `\str_if_eq:NN` is different from `\tl_if_eq:NN` because it needs to ignore category codes.

`\str_if_eq:NNTF`

`\str_if_eq_p:nn` `\prg_new_conditional:Npnn \str_if_eq:NN #1#2 { p , TF , T , F }`

`\str_if_eq_x_p:nn` `{`

`\str_if_eq:nnTF` `\if_int_compare:w \pdfTEX_strcmp:D { \tl_to_str:N #1 } { \tl_to_str:N #2 }`

`\str_if_eq_x:nnTF` `= \c_zero \prg_return_true: \else: \prg_return_false: \fi:`

`}`

(End definition for `\str_if_eq:NN` These functions are documented on page 5.)

`\str_case:nnn` Defined in `l3basics` at present.

`\str_case:onnn` (End definition for `\str_case:nnn`, `\str_case:onnn`, and `\str_case_x:nnn` These functions are documented on page 6.)

`\str_case_x:nnnn`

`\_str_if_contains_char:NNT` Converts the *token list* to a *string* and tests whether the *char* is present in the *string*. Spaces are ignored. Loop over the characters of the string, comparing character codes. The loop is broken if character codes match. Otherwise we return “false”.

`\_str_if_contains_char:NNTF`

`\_str_if_contains_char:NNTF`

```

343 \prg_new_conditional:Npnn \_str_if_contains_char:NN #1#2 { T , TF }
344 {
345   \exp_after:wN \_str_if_contains_char_aux:NN \exp_after:wN #2
346   \etex_detokenize:D \exp_after:wN {#1} { \_prg_break:n { ? \fi: } }
347   \_prg_break_point:
348   \prg_return_false:

```

```

349 }
350 \prg_new_conditional:Npnn \__str_if_contains_char:nN #1#2 { TF }
351 {
352   \exp_after:wN \__str_if_contains_char_aux:NN \exp_after:wN #2
353   \tl_to_str:n {#1} { \__prg_break:n { ? \fi: } }
354   \__prg_break_point:
355   \prg_return_false:
356 }
357 \cs_new:Npn \__str_if_contains_char_aux:NN #1#2
358 {
359   \if_charcode:w #1 #2
360   \exp_after:wN \__str_if_contains_char_true:
361   \fi:
362   \__str_if_contains_char_aux:NN #1
363 }
364 \cs_new_nopar:Npn \__str_if_contains_char_true:
365 { \__prg_break:n { \prg_return_true: \use_none:n } }

```

(End definition for \\_\_str\_if\_contains\_char:NNT and \\_\_str\_if\_contains\_char:NNTF These functions are documented on page ??.)

`\__str_octal_use:NNTF` If the *<token>* is an octal digit, it is left in the input stream, *followed* by the *<true code>*. Otherwise, the *<>false code>* is left in the input stream.

**T<sub>E</sub>Xhackers note:** This function will fail if the escape character is an octal digit. We are thus careful to set the escape character to a known value before using it. T<sub>E</sub>X dutifully detects octal digits for us: if #1 is an octal digit, then the right-hand side of the comparison is '1#1, greater than 1. Otherwise, the right-hand side stops as '1, and the conditional takes the **false** branch.

```

366 \prg_new_conditional:Npnn \__str_octal_use:N #1 { TF }
367 {
368   \if_int_compare:w \c_one < '1 \token_to_str:N #1 \exp_stop_f:
369   #1 \prg_return_true:
370   \else:
371   \prg_return_false:
372   \fi:
373 }

```

(End definition for \\_\_str\_octal\_use:NNTF)

`\__str_hexadecimal_use:NNTF` T<sub>E</sub>X detects uppercase hexadecimal digits for us (see \\_\_str\_octal\_use:NNTF), but not the lowercase letters, which we need to detect and replace by their uppercase counterpart.

```

374 \prg_new_conditional:Npnn \__str_hexadecimal_use:N #1 { TF }
375 {
376   \if_int_compare:w \c_two < "1 \token_to_str:N #1 \exp_stop_f:
377   #1 \prg_return_true:
378   \else:
379     \if_case:w \__int_eval:w
380     \exp_after:wN ' \token_to_str:N #1 - 'a
381     \__int_eval_end:

```

```

382         A
383     \or: B
384     \or: C
385     \or: D
386     \or: E
387     \or: F
388     \else:
389         \prg_return_false:
390         \exp_after:wN \use_none:n
391     \fi:
392     \prg_return_true:
393     \fi:
394 }

```

(End definition for \\_str\_hexadecimal\_use:NTF)

## 9.4 Viewing strings

\str\_show:n Displays a string on the terminal.

```

\str_show:N 395 \cs_new_eq:NN \str_show:n \tl_show:n
\str_show:c 396 \cs_new_eq:NN \str_show:N \tl_show:N
397 \cs_generate_variant:Nn \str_show:N { c }

```

(End definition for \str\_show:n, \str\_show:N, and \str\_show:c These functions are documented on page ??.)

## 9.5 Conversions

### 9.5.1 Producing one byte or character

\c\_\_str\_byte\_0\_tl For each integer  $N$  in the range  $[0, 255]$ , we create a constant token list which holds three character tokens with category code other: the character with character code  $N$ , followed by the representation of  $N$  as two hexadecimal digits. The value  $-1$  is given a default token list which ensures that later functions give an empty result for the input  $-1$ .

```

398 \group_begin:
399   \char_set_catcode_other:n { \c_zero }
400   \tl_set:Nx \l__str_internal_tl { \tl_to_str:n { 0123456789ABCDEF } }
401   \exp_args:No \tl_map_inline:nn { \l__str_internal_tl " }
402     { \char_set_lccode:nn {'#1} { \c_zero } }
403   \tl_map_inline:Nn \l__str_internal_tl
404     {
405       \tl_map_inline:Nn \l__str_internal_tl
406       {
407         \char_set_lccode:nn { \c_zero } {"#1##1}
408         \tl_to_lowercase:n
409         {
410           \tl_const:cx
411             { c__str_byte_ \int_eval:n {"#1##1} _tl }
412             { ^^@ #1 ##1 }
413         }
414     }

```

```

415     }
416 \group_end:
417 \tl_const:cn { c__str_byte_1_tl } { { } \use_none:n { } }
(End definition for \c__str_byte_0_tl, \c__str_byte_1_tl, and \c__str_byte_255_tl These functions
are documented on page ??.)

```

**\\_\_str\_output\_byte:n** Those functions must be used carefully: feeding them a value outside the range  $[-1, 255]$  will attempt to use the undefined token list variable `\c__str_byte_⟨number⟩_tl`. Assuming that the argument is in the right range, we expand the corresponding token list, and pick either the byte (first token) or the hexadecimal representations (second and third tokens). The value  $-1$  produces an empty result in both cases.

```

\__str_output_byte:w
\__str_output_hexadecimal:n
\__str_output_hexadecimal:w
\__str_output_end:
418 \cs_new:Npn \__str_output_byte:n #1
419 { \__str_output_byte:w #1 \__str_output_end: }
420 \cs_new_nopar:Npn \__str_output_byte:w
421 {
422   \exp_after:wN \exp_after:wN
423   \exp_after:wN \use_i:nnn
424   \cs:w c__str_byte_ \int_use:N \__int_eval:w
425 }
426 \cs_new:Npn \__str_output_hexadecimal:n #1
427 { \__str_output_hexadecimal:w #1 \__str_output_end: }
428 \cs_new_nopar:Npn \__str_output_hexadecimal:w
429 {
430   \exp_after:wN \exp_after:wN
431   \exp_after:wN \use_none:n
432   \cs:w c__str_byte_ \int_use:N \__int_eval:w
433 }
434 \cs_new_nopar:Npn \__str_output_end:
435 { \__int_eval_end: _tl \cs_end: }

```

(End definition for \\_\_str\_output\_byte:n This function is documented on page ??.)

**\\_\_str\_output\_byte\_pair\_be:n** Convert a number in the range  $[0, 65535]$  to a pair of bytes, either big-endian or little-endian.

```

\__str_output_byte_pair_le:n
\__str_output_byte_pair:nnN
436 \cs_new:Npn \__str_output_byte_pair_be:n #1
437 {
438   \exp_args:Nf \__str_output_byte_pair:nnN
439   { \int_div_truncate:nn { #1 } { "100 } } {#1} \use:nn
440 }
441 \cs_new:Npn \__str_output_byte_pair_le:n #1
442 {
443   \exp_args:Nf \__str_output_byte_pair:nnN
444   { \int_div_truncate:nn { #1 } { "100 } } {#1} \use_ii_i:nn
445 }
446 \cs_new:Npn \__str_output_byte_pair:nnN #1#2#3
447 {
448   #3
449   { \__str_output_byte:n { #1 } }
450   { \__str_output_byte:n { #2 - #1 * "100 } }
451 }

```

(End definition for \\_\_str\_output\_byte\_pair\_be:n This function is documented on page ??.)

### 9.5.2 Mapping functions for conversions

`\__str_convert_gmap:N` This maps the function #1 over all characters in `\g__str_result_tl`, which should be a byte string in most cases, sometimes a native string.  
`\__str_convert_gmap_loop:NN`

```
452 \cs_new_protected:Npn \__str_convert_gmap:N #1
453 {
454   \tl_gset:Nx \g__str_result_tl
455   {
456     \exp_after:wN \__str_convert_gmap_loop:NN
457     \exp_after:wN #1
458     \g__str_result_tl { ? \__prg_break: }
459     \__prg_break_point:
460   }
461 }
462 \cs_new:Npn \__str_convert_gmap_loop:NN #1#2
463 {
464   \use_none:n #2
465   #1#2
466   \__str_convert_gmap_loop:NN #1
467 }
```

*(End definition for \\_\_str\_convert\_gmap:N This function is documented on page ??.)*

`\__str_convert_gmap_internal:N` This maps the function #1 over all character codes in `\g__str_result_tl`, which must be in the internal representation.  
`\__str_convert_gmap_internal_loop:Nw`

```
468 \cs_new_protected:Npn \__str_convert_gmap_internal:N #1
469 {
470   \tl_gset:Nx \g__str_result_tl
471   {
472     \exp_after:wN \__str_convert_gmap_internal_loop:Nww
473     \exp_after:wN #1
474     \g__str_result_tl \s__tl \q_stop \__prg_break: \s__tl
475     \__prg_break_point:
476   }
477 }
478 \cs_new:Npn \__str_convert_gmap_internal_loop:Nww #1 #2 \s__tl #3 \s__tl
479 {
480   \use_none_delimit_by_q_stop:w #3 \q_stop
481   #1 {#3}
482   \__str_convert_gmap_internal_loop:Nww #1
483 }
```

*(End definition for \\_\_str\_convert\_gmap\_internal:N This function is documented on page ??.)*

### 9.5.3 Error-reporting during conversion

`\__str_if_flag_error:nmx` When converting using the function `\str_set_convert:Nnnn`, errors should be reported to the user after each step in the conversion. Errors are signalled by raising some flag (typically `@@_error`), so here we test that flag: if it is raised, give the user an error,  
`\__str_if_flag_no_error:nmx`

otherwise remove the arguments. On the other hand, in the conditional functions `\str_set_convert:NnnnTF`, errors should be suppressed. This is done by changing `\__str_if_flag_error:nxx` into `\__str_if_flag_no_error:nxx` locally.

```

484 \cs_new_protected:Npn \__str_if_flag_error:nxx #1
485 {
486   \flag_if_raised:nTF {#1}
487   { \__msg_kernel_error:nxx { str } }
488   { \use_none:nn }
489 }
490 \cs_new_protected:Npn \__str_if_flag_no_error:nxx #1#2#3
491 { \flag_if_raised:nT {#1} { \bool_gset_true:N \g__str_error_bool } }
(End definition for \__str_if_flag_error:nxx This function is documented on page ??.)

```

`\__str_if_flag_times:nT` At the end of each conversion step, we raise all relevant errors as one error message, built on the fly. The height of each flag indicates how many times a given error was encountered. This function prints `#2` followed by the number of occurrences of an error if it occurred, nothing otherwise.

```

492 \cs_new_protected:Npn \__str_if_flag_times:nT #1#2
493 { \flag_if_raised:nT {#1} { #2~(x \flag_height:n {#1} ) } }
(End definition for \__str_if_flag_times:nT This function is documented on page ??.)

```

#### 9.5.4 Framework for conversions

Most functions in this module expect to be working with “native” strings. Strings can also be stored as bytes, in one of many encodings, for instance UTF8. The bytes themselves can be expressed in various ways in terms of  $\text{\TeX}$  tokens, for instance as pairs of hexadecimal digits. The questions of going from arbitrary Unicode code points to bytes, and from bytes to tokens are mostly independent.

Conversions are done in four steps:

- “unescape” produces a string of bytes;
- “decode” takes in a string of bytes, and converts it to a list of Unicode characters in an internal representation, with items of the form

$$\langle \text{bytes} \rangle \backslash \text{s\_t1} \langle \text{Unicode code point} \rangle \backslash \text{s\_t1}$$

where we have collected the  $\langle \text{bytes} \rangle$  which combined to form this particular Unicode character, and the  $\langle \text{Unicode code point} \rangle$  is in the range  $[0, "10FFFF]$ .

- “encode” encodes the internal list of code points as a byte string in the new encoding;
- “escape” escapes bytes as requested.

The process is modified in case one of the encoding is empty (or the conversion function has been set equal to the empty encoding because it was not found): then the unescape or escape step is ignored, and the decode or encode steps work on tokens instead of bytes. Otherwise, each step must ensure that it passes a correct byte string or internal string to the next step.

```

\str_set_convert:Nnnn
\str_gset_convert:Nnnn
\str_set_convert:NnnnTF
\str_gset_convert:NnnnTF
__str_convert_i:nNNnnn

```

The input string is stored in `\g__str_result_tl`, then we: unescape and decode; encode and escape; exit the group and store the result in the user's variable. The various conversion functions all act on `\g__str_result_tl`. Errors are silenced for the conditional functions by redefining `\__str_if_flag_error:nxx` locally.

```

494 \cs_new_protected_nopar:Npn \str_set_convert:Nnnn
495   { \__str_convert_i:nNNnnn { } \tl_set_eq:NN }
496 \cs_new_protected_nopar:Npn \str_gset_convert:Nnnn
497   { \__str_convert_i:nNNnnn { } \tl_gset_eq:NN }

526     \exp_after:wN \__str_convert_ii:wwwnn
527     \tl_to_str:n {#6} /// \q_stop
528     { encode } { escape }
529     \use_ii_i:nn
530     \__str_convert_encode_:
531     \group_end:
532     #2 #3 \g__str_result_tl
533   }

```

(End definition for `\str_set_convert:Nnnn` and `\str_gset_convert:Nnnn` These functions are documented on page 8.)

```

__str_convert_ii:wwwnn
__str_convert_iii:NNnNN

```

The task of `\__str_convert_ii:wwwnn` is to split  $\langle encoding \rangle / \langle escaping \rangle$  pairs into their components, #1 and #2. Calls to `\__str_convert_iv:nnn` ensure that the corresponding

conversion functions are defined. The third auxiliary does the main work.

- #1 is the encoding conversion function;
- #2 is the escaping function;
- #3 is the escaping name for use in an error message;
- #4 is `\prg_do_nothing:` for unescaping/decoding, and `\use_ii_i:nn` for encoding/escaping;
- #5 is the default encoding function (either “decode” or “encode”), for which there should be no escaping.

Let us ignore the native encoding for a second. In the unescaping/decoding phase, we want to do #2#1 in this order, and in the encoding/escaping phase, the order should be reversed: #4#2#1 does exactly that. If one of the encodings is the default (native), then the escaping should be ignored, with an error if any was given, and only the encoding, #1, should be performed.

```

534 \cs_new_protected:Npn \__str_convert_ii:wwwnn
535   #1 / #2 // #3 \q_stop #4#5
536   {

(End definition for `\__str_convert_ii:wwwnn` This function is documented on page 8.)

`\__str_convert_iv:nnn` The arguments of `\__str_convert_iv:nnn` are: `enc` or `esc`, used to build filenames, the type of the conversion (unescape, decode, encode, escape), and the encoding or escaping name. If the function is already defined, no need to do anything. Otherwise, filter out all non-alphanumerics in the name, and lowercase it. Feed that, and the same three arguments, to `\__str_convert_v:nnnn`. The task is then to make sure that the conversion function `#3_#1` corresponding to the type `#3` and filtered name `#1` is defined, then set our initial conversion function `#3_#4` equal to that.

How do we get the `#3_#1` conversion to be defined if it isn't? Two main cases.

First, if `#1` is a key in `\g__str_alias_prop`, then the value `\l__str_internal_tl` tells us what file to load. Loading is skipped if the file was already read, *i.e.*, if the

conversion command based on `\l__str_internal_tl` already exists. Otherwise, try to load the file; if that fails, there is an error, use the default empty name instead.

Second, `#1` may be absent from the property list. The `\cs_if_exist:cF` test is automatically false, and we search for a file defining the encoding or escaping `#1` (this should allow third-party `.def` files). If the file is not found, there is an error, use the default empty name instead.

In all cases, the conversion based on `\l__str_internal_tl` is defined, so we can set the `#3_#1` function equal to that. In some cases (*e.g.*, `utf16be`), the `#3_#1` function is actually defined within the file we just loaded, and it is different from the `\l__str_internal_tl`-based function: we mustn't clobber that different definition.

### 9.5.5 Byte unescape and escape

Strings of bytes may need to be stored in auxiliary files in safe “escaping” formats. Each such escaping is only loaded as needed. By default, on input any non-byte is filtered out, while the output simply consists in letting bytes through.

`\__str_filter_bytes:n` In the case of pdfTeX, every character is a byte. For Unicode-aware engines, test the character code; non-bytes cause us to raise the flag `str_byte`. Spaces have already been given the correct category code when this function is called.

```

634 \pdfTeX_if_engine:TF
635 { \cs_new_eq:NN \__str_filter_bytes:n \use:n }
636 {
637   \cs_new:Npn \__str_filter_bytes:n #1
638   {
639     \__str_filter_bytes_aux:N #1
640     { ? \__prg_break: }
641     \__prg_break_point:
642   }
643   \cs_new:Npn \__str_filter_bytes_aux:N #1
644   {
645     \use_none:n #1
646     \if_int_compare:w '#1 < 256 \exp_stop_f:
647     #1
648     \else:
649       \flag_raise:n { str_byte }
650     \fi:
651     \__str_filter_bytes_aux:N
652   }
653 }

```

(End definition for `\__str_filter_bytes:n` This function is documented on page ??.)

`\__str_convert_unescape_:` The simplest unescaping method removes non-bytes from `\g__str_result_tl`.

```

\__str_convert_unescape_bytes:
654 \pdfTeX_if_engine:TF
655 { \cs_new_protected_nopar:Npn \__str_convert_unescape_: { } }
656 {
657   \cs_new_protected_nopar:Npn \__str_convert_unescape_:
658   {
659     \flag_clear:n { str_byte }
660     \tl_gset:Nx \g__str_result_tl
661     { \exp_args:No \__str_filter_bytes:n \g__str_result_tl }
662     \__str_if_flag_error:nx { str_byte } { non-byte } { bytes }
663   }
664 }
665 \cs_new_eq:NN \__str_convert_unescape_bytes: \__str_convert_unescape_:

```

(End definition for `\__str_convert_unescape_`: This function is documented on page ??.)

`\__str_convert_escape_`: The simplest form of escape leaves the bytes from the previous step of the conversion  
`\__str_convert_escape_bytes`: unchanged.

```
666 \cs_new_protected_nopar:Npn \__str_convert_escape_: { }
667 \cs_new_eq:NN \__str_convert_escape_bytes: \__str_convert_escape_:
```

(End definition for `\__str_convert_escape_`: This function is documented on page ??.)

### 9.5.6 Native strings

`\__str_convert_decode_`: Convert each character to its character code, one at a time.  
`\__str_decode_native_char:N`

```
668 \cs_new_protected_nopar:Npn \__str_convert_decode_:
669   { \__str_convert_gmap:N \__str_decode_native_char:N }
670 \cs_new:Npn \__str_decode_native_char:N #1
671   { #1 \s__tl \__int_value:w '#1 \s__tl }
```

(End definition for `\__str_convert_decode_`: This function is documented on page ??.)

`\__str_convert_encode_`: The conversion from an internal string to native character tokens is very different in pdfTeX and in other engines. For Unicode-aware engines, we need the definitions to be read when the null byte has category code 12, so we set that inside a group.

```
672 \group_begin:
673   \char_set_catcode_other:n { 0 }
674   \pdfTeX_if_engine:TF
```

`\__str_encode_native_char:n` Since pdfTeX only supports 8-bit characters, and we have a table of all bytes, the conversion can be done in linear time within an x-expanding assignment. Look out for character codes larger than 255, those characters are replaced by ?, and raise a flag, which then triggers a pdfTeX-specific error.

```
675   {
676     \cs_new_protected_nopar:Npn \__str_convert_encode_:
677       {
678         \flag_clear:n { str_error }
679         \__str_convert_gmap_internal:N \__str_encode_native_char:n
680         \__str_if_flag_error:nx { str_error }
681         { pdfTeX-native-overflow } { }
682       }
683     \cs_new:Npn \__str_encode_native_char:n #1
684       {
685         \if_int_compare:w #1 < \c_two_hundred_fifty_six
686           \__str_output_byte:n {#1}
687         \else:
688           \flag_raise:n { str_error }
689           ?
690         \fi:
691       }
692     \__msg_kernel_new:nnnn { str } { pdfTeX-native-overflow }
693     { Character-code-too-large-for-pdfTeX. }
694     {
```

```

695         The~pdfTeX-engine-only~supports~8-bit-characters::~
696         valid-character-codes~are~in~the~range~[0,255].~
697         To~manipulate~arbitrary~Unicode,~use~LuaTeX~or~XeTeX.
698     }
699 }

```

```

__str_encode_native_loop:w
__str_encode_native_flush:
    __str_encode_native_filter:N

```

In Unicode-aware engines, since building particular characters cannot be done expandably in T<sub>E</sub>X, we cannot hope to get a linear-time function. However, we get quite close using the l3tl-build module, which abuses \toks to reach an almost linear time. Use the standard lowercase trick to produce an arbitrary character from the null character, and add that character to the end of the token list being built. At the end of the loop, put the token list together with \\_\_tl\_build\_end:. Note that we use an x-expanding assignment because it is slightly faster. Unicode-aware engines will never incur an overflow because the internal string is guaranteed to only contain code points in [0, "10FFFF].

```

700 {
701     \cs_new_protected_nopar:Npn \__str_convert_encode_:
702     {
703         \int_zero:N \l__tl_build_offset_int
704         \__tl_gbuild_x:Nw \g__str_result_tl
705         \exp_after:wN \__str_encode_native_loop:w
706         \g__str_result_tl \s__tl { \q_stop \__prg_break: } \s__tl
707         \__prg_break_point:
708         \__tl_build_end:
709     }
710     \cs_new_protected:Npn \__str_encode_native_loop:w #1 \s__tl #2 \s__tl
711     {
712         \use_none_delimit_by_q_stop:w #2 \q_stop
713         \tex_lccode:D \l__str_internal_int \__int_eval:w #2 \__int_eval_end:
714         \tl_to_lowercase:n { \__tl_build_one:n { ^~@ } }
715         \__str_encode_native_loop:w
716     }
717 }

```

End the group to restore the catcode of the null byte.

```

718 \group_end:

```

(End definition for \\_\_str\_convert\_encode\_: This function is documented on page ??.)

### 9.5.7 8-bit encodings

This section will be entirely rewritten: it is not yet clear in what situations 8-bit encodings are used, hence I don't know what exactly should be optimized. The current approach is reasonably efficient to convert long strings, and it scales well when using many different encodings. An approach based on csnames would have a smaller constant load time for each individual conversion, but has a large hash table cost. Using a range of \count registers works for decoding, but not for encoding: one possibility there would be to use a binary tree for the mapping of Unicode characters to bytes, stored as a box, one per encoding.

Since the section is going to be rewritten, documentation lacks.

All the 8-bit encodings which l3str supports rely on the same internal functions.

`\_str_declare_eight_bit_encoding:nnn` This declares the encoding  $\langle name \rangle$  to map bytes to Unicode characters according to the  $\langle mapping \rangle$ , and map those bytes which are not mentioned in the  $\langle mapping \rangle$  either to the replacement character (if they appear in  $\langle missing \rangle$ ), or to themselves.

All the 8-bit encoding definition file start with `\_str_declare_eight_bit_encoding:nnn`  $\{\langle encoding name \rangle\}$   $\{\langle mapping \rangle\}$   $\{\langle missing bytes \rangle\}$ . The  $\langle mapping \rangle$  argument is a token list of pairs  $\{\langle byte \rangle\}$   $\{\langle Unicode \rangle\}$  expressed in uppercase hexadecimal notation. The  $\langle missing \rangle$  argument is a token list of  $\{\langle byte \rangle\}$ . Every  $\langle byte \rangle$  which does not appear in the  $\langle mapping \rangle$  nor the  $\langle missing \rangle$  lists maps to the same code point in Unicode.

```

## 9.6 Messages

General messages, and messages for the encodings and escapings loaded by default (“native”, and “bytes”).

```

820 \__msg_kernel_new:nnn { str } { unknown-esc }
821 { Escaping~scheme~'#1'~(filtered:~'#2')~unknown. }
822 \__msg_kernel_new:nnn { str } { unknown-enc }
823 { Encoding~scheme~'#1'~(filtered:~'#2')~unknown. }
824 \__msg_kernel_new:nnnn { str } { native-escaping }
825 { The~'native'~encoding~scheme~does~not~support~any~escaping. }
826 {
827   Since~native~strings~do~not~consist~in~bytes,~
828   none~of~the~escaping~methods~make~sense.~
829   The~specified~escaping,~'#1',~will be ignored.
830 }
831 \__msg_kernel_new:nnn { str } { file-not-found }
832 { File~'l3str-#1.def'~not~found. }

```

Message used when the “bytes” unescaping fails because the string given to `\str_set_convert:Nnnn` contains a non-byte. This cannot happen for the pdfTeX engine, since that engine only supports 8-bit characters. Messages used for other escapings and encodings are defined in each definition file.

```

833 \pdfTeX_if_engine:F
834 {
835   \__msg_kernel_new:nnnn { str } { non-byte }
836   { String~invalid~in~escaping~'#1':~it~may~only~contain~bytes. }
837   {
838     Some~characters~in~the~string~you~asked~to~convert~are~not~
839     8-bit~characters.~Perhaps~the~string~is~a~'native'~Unicode~string?~
840     If~it~is,~try~using\\
841     \\

```

```

842         \iow_indent:n
843         {
844             \iow_char:N\str_set_convert:Nnnn \
845             \ \ <str-var>~\{<string>~\}~\{~native~\}~\{<target-encoding>~\}
846         }
847     }
848 }

```

Those messages are used when converting to and from 8-bit encodings.

```

849 \__msg_kernel_new:nnnn { str } { decode-8-bit }
850 { Invalid~string~in~encoding~'#1'. }
851 {
852     LaTeX~came~across~a~byte~which~is~not~defined~to~represent~
853     any~character~in~the~encoding~'#1'.
854 }
855 \__msg_kernel_new:nnnn { str } { encode-8-bit }
856 { Unicode~string~cannot~be~converted~to~encoding~'#1'. }
857 {
858     The~encoding~'#1'~only~contains~a~subset~of~all~Unicode~characters.~
859     LaTeX~was~asked~to~convert~a~string~to~that~encoding,~but~that~
860     string~contains~a~character~that~'#1'~does~not~support.
861 }

```

## 9.7 Deprecated string functions

Deprecated 2012-05-13 for removal by 2012-08-31.

are documented on page ??.)
865 </initex | package>

```

## 9.8 Escaping definition files

Several of those encodings are defined by the pdf file format. The following byte storage methods are defined:

- **bytes** (default), non-bytes are filtered out, and bytes are left untouched (this is defined by default);
- **hex** or **hexadecimal**, as per the pdfTeX primitive `\pdfescapehex`
- **name**, as per the pdfTeX primitive `\pdfescapename`
- **string**, as per the pdfTeX primitive `\pdfescapestring`
- **url**, as per the percent encoding of urls.

### 9.8.1 Unescape methods

`\\_str_convert_unescape_hex:` Take chars two by two, and interpret each pair as the hexadecimal code for a byte.  
`\\_str_unescape_hex_i:N` Anything else than hexadecimal digits is ignored, raising the flag. A string which contains  
`\\_str_unescape_hex_ii:N` an odd number of hexadecimal digits gets 0 appended to it: this is equivalent to appending  
a 0 in all cases, and dropping it if it is alone.

```

866 <*hex>

```

(End definition for `\__str_convert_unescape_hex`: This function is documented on page ??.)

`\__str_convert_unescape_name`: The `\__str_convert_unescape_name`: function replaces each occurrence of # followed by two hexadecimal digits in `\g__str_result_tl` by the corresponding byte. The `url` function is identical, with escape character % instead of #. Thus we define the two together. The arguments of `\__str_tmp:w` are the character code of # or % in hexadecimal, the name of the main function to define, and the name of the auxiliary which performs the loop.

The looping auxiliary #3 finds the next escape character, reads the following two characters, and tests them. The test `\__str_hexadecimal_use:NTF` leaves the upper-case digit in the input stream, hence we surround the test with `\__str_output_byte:w` and `\__str_output_end:`. If both characters are hexadecimal digits, they should be removed before looping: this is done by `\use_i:nnn`. If one of the characters is not a hexadecimal digit, then feed "#1 to `\__str_output_byte:w` to produce the escape character, raise the flag, and call the looping function followed by the two characters (remove `\use_i:nnn`).

```

969 </url>

```

(End definition for `\__str_convert_unescape_name`: This function is documented on page ??.)

`\_str_convert_unescape_string:` The **string** escaping is somewhat similar to the **name** and **url** escapings, with escape character `\`. The first step is to convert all three line endings, `^^J`, `^^M`, and `^^M^^J` to the common `^^J`, as per the PDF specification. This step cannot raise the flag.

`\_str_unescape_string_newlines:wN`

`\_str_unescape_string_loop:wNNN`

`\_str_unescape_string_repeat:NNNNNN`

Then the following escape sequences are decoded.

- `\n` Line feed (10)
- `\r` Carriage return (13)
- `\t` Horizontal tab (9)
- `\b` Backspace (8)
- `\f` Form feed (12)
- `\(` Left parenthesis
- `\)` Right parenthesis
- `\\` Backslash

`\ddd` (backslash followed by 1 to 3 octal digits) Byte `ddd` (octal), subtracting 256 in case of overflow.

If followed by an end-of-line character, the backslash and the end-of-line are ignored. If followed by anything else, the backslash is ignored, raising the error flag.

## 9.9 Encoding definition files

The **native** encoding is automatically defined. Other encodings are loaded as needed. The following encodings are supported:

- UTF-8;
- UTF-16, big-, little-endian, or with byte order mark;
- UTF-32, big-, little-endian, or with byte order mark;
- the ISO 8859 code pages, numbered from 1 to 16, skipping the inexistent ISO 8859-12.

### 9.9.1 utf-8 support

```

1147 <*utf8>

```

`\__str_convert_encode_utf8:` Loop through the internal string, and convert each character to its UTF-8 representation.  
`\_str_encode_utf_viii_char:n` The representation is built from the right-most (least significant) byte to the left-most (most significant) byte. Continuation bytes are in the range [128, 191], taking 64 different values, hence we roughly want to express the character code in base 64, shifting the first digit in the representation by some number depending on how many continuation bytes there are. In the range [0, 127], output the corresponding byte directly. In the range [128, 2047], output the remainder modulo 64, plus 128 as a continuation byte, then output the quotient (which is in the range [0, 31]), shifted by 192. In the next range, [2048, 65535], split the character code into residue and quotient modulo 64, output the residue as a first continuation byte, then repeat; this leaves us with a quotient in the range [0, 15], which we output shifted by 224. The last range, [65536, 1114111], follows the same pattern: once we realize that dividing twice by 64 leaves us with a number larger than 15, we repeat, producing a last continuation byte, and offset the quotient by 240 for the leading byte.

How is that implemented? `\__str_encode_utf_vii_loop:wnnw` takes successive quotients as its first argument, the quotient from the previous step as its second argument (except in step 1), the bound for quotients that trigger one more step or not, and finally the offset used if this step should produce the leading byte. Leading bytes can be in the ranges [0, 127], [192, 223], [224, 239], and [240, 247] (really, that last limit should be 244 because Unicode stops at the code point 1114111). At each step, if the quotient #1 is less than the limit #3 for that range, output the leading byte (#1 shifted by #4)

and stop. Otherwise, we need one more step: use the quotient of #1 by 64, and #1 as arguments for the looping auxiliary, and output the continuation byte corresponding to the remainder  $\#2 - 64\#1 + 128$ . The bizarre construction `\c_minus_one + \c_zero *` removes the spurious initial continuation byte (better methods welcome).

```

`\l__str_missing_flag`  
`\l__str_extra_flag`  
`\l__str_overlong_flag`  
`\l__str_overflow_flag`

When decoding a string that is purportedly in the UTF-8 encoding, four different errors can occur, signalled by a specific flag for each (we define those flags using `\flag_clear_new:n` rather than `\flag_new:n`, because they are shared with other encoding definition files).

- “Missing continuation byte”: a leading byte is not followed by the right number of continuation bytes.
- “Extra continuation byte”: a continuation byte appears where it was not expected, *i.e.*, not after an appropriate leading byte.
- “Overlong”: a Unicode character is expressed using more bytes than necessary, for instance, “C0”80 for the code point 0, instead of a single null byte.
- “Overflow”: this occurs when decoding produces Unicode code points greater than 1114111.

We only raise one L<sup>A</sup>T<sub>E</sub>X3 error message, combining all the errors which occurred. In the short message, the leading comma must be removed to get a grammatically correct sentence. In the long text, first remind the user what a correct UTF-8 string should look like, then add error-specific information.

(End definition for \l\_\_str\_missing\_flag and others. These variables are documented on page ??.)

`\__str_convert_decode_utf8:` Decoding is significantly harder than encoding. As before, lower some flags, which are tested at the end (in bulk, to trigger at most one L<sup>A</sup>T<sub>E</sub>X3 error, as explained above). We expect successive multi-byte sequences of the form  $\langle start\ byte \rangle \langle continuation\ bytes \rangle$ . The `_start` auxiliary tests the first byte:

`\_str_decode_utf_viii_start:N`

`\_str_decode_utf_viii_continuation:wN`

`\_str_decode_utf_viii_aux:wNnnwN`

`\_str_decode_utf_viii_overflow:w`

`\__str_decode_utf_viii_end:`

- `[0, "7F]`: the byte stands alone, and is converted to its own character code;
- `["80, "BF]`: unexpected continuation byte, raise the appropriate flag, and convert that byte to the replacement character "FFFD;
- `["C0, "FF]`: this byte should be followed by some continuation byte(s).

In the first two cases, `\use_none_delimit_by_q_stop:w` removes data that only the third case requires, namely the limits of ranges of Unicode characters which can be expressed with 1, 2, 3, or 4 bytes.

We can now concentrate on the multi-byte case and the `_continuation` auxiliary. We expect `#3` to be in the range `["80, "BF]`. The test for this goes as follows: if the character code is less than "80, we compare it to `-"C0`, yielding `false`; otherwise to `"C0`, yielding `true` in the range `["80, "BF]` and `false` otherwise. If we find that the byte is not a continuation range, stop the current slew of bytes, output the replacement character, and continue parsing with the `_start` auxiliary, starting at the byte we just tested. Once we know that the byte is a continuation byte, leave it behind us in the input stream, compute what code point the bytes read so far would produce, and feed that number to the `_aux` function.

The `_aux` function tests whether we should look for more continuation bytes or not. If the number it receives as `#1` is less than the maximum `#4` for the current range, then we are done: check for an overlong representation by comparing `#1` with the maximum `#3` for the previous range. Otherwise, we call the `_continuation` auxiliary again, after shifting the “current code point” by `#4` (maximum from the range we just checked).

Two additional tests are needed: if we reach the end of the list of range maxima and we are still not done, then we are faced with an overflow. Clean up, and again insert the code point "FFFD for the replacement character. Also, every time we read a byte, we need to check whether we reached the end of the string. In a correct UTF-8 string, this happens automatically when the `_start` auxiliary leaves its first argument in the input stream: the end-marker begins with `\__prg_break:`, which ends the loop. On the other hand, if the end is reached when looking for a continuation byte, the `\use_none:n #3` construction removes the first token from the end-marker, and leaves the `_end` auxiliary, which raises the appropriate error flag before ending the mapping.

### 9.9.2 utf-16 support

The definitions are done in a category code regime where the bytes 254 and 255 used by the byte order mark have catcode 12.

```

1314 <*utf16>
1315 \group_begin:
1316 \char_set_catcode_other:N \^^fe
1317 \char_set_catcode_other:N \^^ff

```

\\_\_str\_convert\_encode\_utf16: When the endianness is not specified, it is big-endian by default, and we add a byte-order mark. Convert characters one by one in a loop, with different behaviours depending on

```

\__str_convert_encode_utf16be:
\__str_convert_encode_utf16le:
\__str_encode_utf_xvi_aux:N
\__str_encode_utf_xvi_char:n

```

the character code.

- [0, "D7FF]: converted to two bytes;
- ["D800, "DFFF] are used as surrogates: they cannot be converted and are replaced by the replacement character;
- ["E000, "FFFF]: converted to two bytes;
- ["10000, "10FFFF]: converted to a pair of surrogates, each two bytes. The magic "D7C0 is "D800 – "10000/"400.

For the duration of this operation, `__str_tmp:w` is defined as a function to convert a number in the range [0, "FFFF] to a pair of bytes (either big endian or little endian), by feeding the quotient of the division of #1 by "100, followed by #1 to `__str_encode_utf_xvi_be:nn` or its `le` analog: those compute the remainder, and output two bytes for the quotient and remainder.

 These functions are documented on page ??.)

`\l__str_missing_flag` When encoding a Unicode string to UTF-16, only one error can occur: code points in  
`\l__str_extra_flag` the range ["D800,"DFFF], corresponding to surrogates, cannot be encoded. We use the  
`\l__str_end_flag` all-purpose flag `@@_error` to signal that error.

When decoding a Unicode string which is purportedly in UTF-16, three errors can occur: a missing trail surrogate, an unexpected trail surrogate, and a string containing an odd number of bytes.

`\__str_convert_decode_utf16:` As for UTF-8, decoding UTF-16 is harder than encoding it. If the endianness is unknown, check the first two bytes: if those are "FE and "FF in either order, remove them and use the corresponding endianness, otherwise assume big-endianness. The three endianness cases are based on a common auxiliary whose first argument is 1 for big-endian and 2 for little-endian, and whose second argument, delimited by the scan mark `\s__stop`, is expanded once (the string may be long; passing `\g__str_result_tl` as an argument before expansion is cheaper).

The `\__str_decode_utf_xvi:Nw` function defines `\__str_tmp:w` to take two arguments and return the character code of the first one if the string is big-endian, and the second one if the string is little-endian, then loops over the string using `\__str_decode_utf_xvi_pair:NN` described below.

```

Bytes are read two at a time. At this stage, `\@@_tmp:w #1#2` expands to the character code of the most significant byte, and we distinguish cases depending on which range it lies in:

- ["D8,"DB] signals a lead surrogate, and the integer expression yields 1 ( $\varepsilon$ -TeX rounds ties away from zero);
- ["DC,"DF] signals a trail surrogate, unexpected here, and the integer expression yields 2;
- any other value signals a code point in the Basic Multilingual Plane, which stands for itself, and the `\if_case:w` construction expands to nothing (cases other than 1 or 2), leaving the relevant material in the input stream, followed by another call to the `_pair` auxiliary.

The case of a lead surrogate is treated by the `_quad` auxiliary, whose arguments `#1`, `#2`, `#4` and `#5` are the four bytes. We expect the most significant byte of `#4#5` to be in the range ["DC,"DF] (trail surrogate). The test is similar to the test used for continuation bytes in the UTF-8 decoding functions. In the case where `#4#5` is indeed a trail surrogate, leave `#1#2#4#5 \s__tl <code point> \s__tl`, and remove the pair `#4#5` before looping with `\_str_decode_utf_xvi_pair:NN`. Otherwise, of course, complain about the missing surrogate.

The magic number "D7F7 is such that "D7F7\*"400 = "D800\*"400+"DC00—"10000.

Every time we read a pair of bytes, we test for the end-marker `\q_nil`. When reaching the end, we additionally check that the string had an even length. Also, if the end is reached when expecting a trail surrogate, we treat that as a missing surrogate.

**str\_overflow** There can be no error when encoding in UTF-32. When decoding, the string may not have length  $4n$ , or it may contain code points larger than "10FFFF". The latter case often happens if the encoding was in fact not UTF-32, because most arbitrary strings are not valid in UTF-32.

**\\_\_str\_convert\_decode\_utf32:** The structure is similar to UTF-16 decoding functions. If the endianness is not given, test the first 4 bytes of the string (possibly `\s__stop` if the string is too short) for the presence of a byte-order mark. If there is a byte-order mark, use that endianness, and remove the 4 bytes, otherwise default to big-endian, and leave the 4 bytes in place. The `\__str_decode_utf_xxxii:Nw` auxiliary receives 1 or 2 as its first argument indicating endianness, and the string to convert as its second argument (expanded or not). It sets `\__str_tmp:w` to expand to the character code of either of its two arguments depending on endianness, then triggers the `_loop` auxiliary inside an x-expanding assignment to `\g__str_result_tl`.

The `_loop` auxiliary first checks for the end-of-string marker `\s__stop`, calling the `_end` auxiliary if appropriate. Otherwise, leave the  $\langle 4 \text{ bytes} \rangle$  `\s__tl` behind, then check that the code point is not overflowing: the leading byte must be 0, and the following byte at most 16.

In the ending code, we check that there remains no byte: there should be nothing left until the first `\s__stop`. Break the map.

```

(End definition for `\__str_convert_decode_utf32:`, `\__str_convert_decode_utf32be:`, and `\__str_convert_decode_utf32l:`. These functions are documented on page ??.)

Restore the original catcodes of bytes 0, 254 and 255.

```

1623 \group_end:
1624 </utf32>

```

#### 9.9.4 iso 8859 support

The ISO-8859-1 encoding exactly matches with the 256 first Unicode characters. For other 8-bit encodings of the ISO-8859 family, we keep track only of differences, and of unassigned bytes.

```
